Privacy should be built into the network, supplied by anyone and paid for by the people who use it

Private by default

Payments, queries and connections should reveal only what their owners choose to share. Disclosure should be something a user decides to make, with an auditor or a regulator, and never a side effect of using the network.

Open supply

Anyone with bandwidth, hardware or code should be able to add capacity from wherever they are. A network that depends on one operator, or one country, can be switched off.

Measured, then paid

Validators should measure what each provider actually delivers, and rewards should follow that measurement. Over time those rewards should come from customers rather than from emissions.

Bittensor showed that an open network can produce intelligence and price it as a commodity. Privacy is the next commodity that belongs on such a network, and SN25 is where it can be supplied, measured and paid for.
